A new explanation for global warming

Light travels at a rate of three hundred million (300,000,000) meters a second or three hundred giga (300,000,000,000) millimeters a second. Recent advances in radio astronomy have developed instruments that can detect this radiation from the sun. This frequency just happens to produce a wavelength of one millimeter and that is just the frequency that microwave ovens produce that heats water in foods. The upper atmosphere is full of water vapor from high flying jets and thus heating of the atmosphere over the last century since the invention of aircraft is a very possible explanation of global warming, particularly over the last 50 years as has been noted in alarming rates. Each jet produces tons of water vapor, just look at the sky for the numerous contrails crossing this area.

With this discovery of millimeter radiation from the sun, wouldn't it be humiliating for those who blame carbon dioxide for global warming to be proven wrong? I was one who thought the problem may have been carbon dioxide and that the sea was the answer to the problem as mother nature has done many times in the past. But with new science, I think I was wrong and accept the new idea of millimeter radiation and water vapor in the upper atmosphere as the most likely cause of global warming.
